1 Introduction

1.1 TRNSYS 18 Background

TRNSYS is a complete, modular, and expansible simulation environment for the transient simulation of thermal systems including multi-zone buildings. It is used by engineers and researchers around the world to validate new energy concepts, from simple solar domestic hot water systems to the design and simulation of buildings and their equipment, including control strategies, occupant behavior, alternative energy systems (wind, solar, photovoltaic, hydrogen systems), etc.

One of the key factors in TRNSYS' success over the last 30 years is its open, modular structure. The source code of the kernel as well as the component models is delivered to the users. This simplifies extending existing models to make them fit the user's specific needs.

The DLL-based architecture allows users and third-party developers to easily add custom component models, using all common programming languages (Python, C, C++, PASCAL, FORTRAN, etc.). In addition, TRNSYS can be easily connected to many other applications, for pre- or post-processing or through interactive calls during the simulation (e.g. Microsoft Excel, Matlab, etc.). TRNSYS applications include:

- Solar systems (solar thermal and PV)
- Low energy buildings and HVAC systems with advanced design features (natural ventilation, slab heating/cooling, double façade, etc.)
- Renewable energy systems
- Cogeneration, fuel cells
- Anything that requires dynamic simulation!

If TRNSYS is used in building design, the multi-zone building model, so-called Type56 is the most important component with integrated models for thermoactivated components and daylight simulation, among other things. In contrast to other components, the building model requires a much more comprehensive and different data set for each building, which contains the entire building description including the time-dependent operation mode. The main interface for creating the building description is called TRNBuild. For more information see the building model manual (\TRNSYS18\Documentation\05-MultizoneBuilding.pdf).

1.2 Trnsys3d Plug-in

To easily generate the geometric information for the building model of TRNSYS (Type 56), the plug-in Trnsys3d for Goggle SketchUp™ has been developed. It allows the user draw the building as well as shading geometry. This means you should have the thermal zoning defined before you start.

This information can be imported in TRNBuild. Note that the plug-in is not a full-featured interface. Non-geometric data, such as materials, controls, internal heat gains, HVAC equipment and systems, etc. are defined in TRNBuild.

The Trnsys3d plug-in is based on the open source legacy plugin of OpenStudio™ (<https://github.com/NREL/legacy-openstudio>). Therefore, it can't be integrated into the TRNSYS package but is available for free download under GNU-GPL.

1.3 New Developments

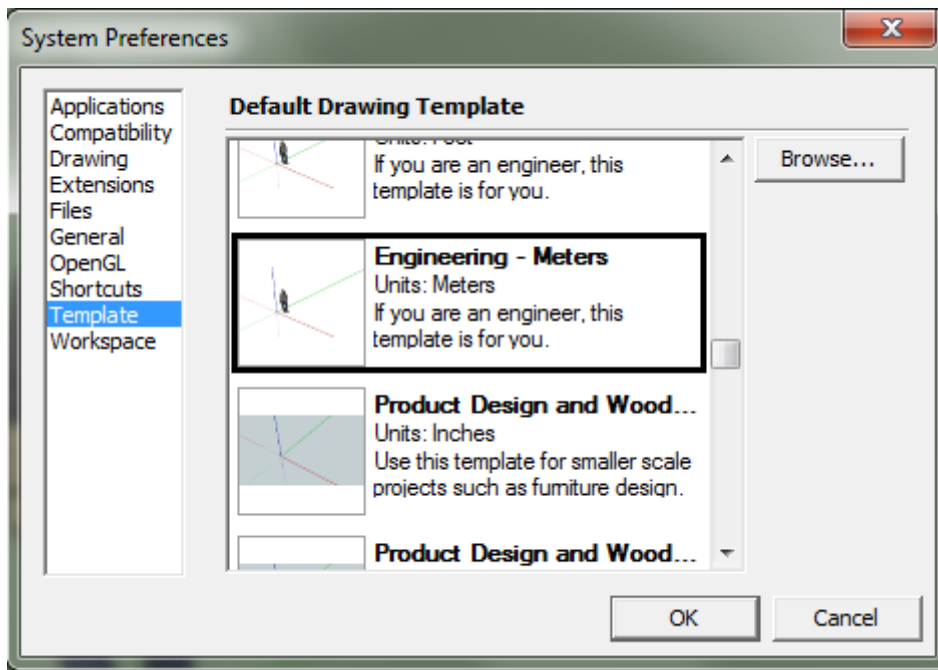

New features for the current Trnsys3d version 1.0.7.1 are listed below:

- Simulation Studio Wizard for Trnsys3d
- Zone templates (generic zone types) for Trnsys3d
- Daylight Controls in Trnsys18

2 Create 3D model with Trnsys3d in SketchUp

2.1 Installation of SketchUp and Trnsys3d Plug-in

- Download and install Google SketchUp from <http://sketchup.google.com/>.
- The installer of Trnsys3d is included in the TRNSYS 18 package (\TRNSYS18\Tools\T3d_setup.exe). In general, the installer is started as Add-on after the TRNSYS 18 installation. If this isn't the case, install trnsys3d manually by executing the T3d_setup.exe. A download link is provided at <https://www.trnsys.de/en/addons-en>
- Start Google Sketchup. If you are starting Google SketchUp for the first time, you will be prompted to choose a Google SketchUp template. Choose the 'Engineering – Meters' template and click 'Start using SketchUp'.
- If you already use SketchUp in IP units, it is recommended that you switch to 'Engineering – Meters' Template. To do this, go to *Window > Preferences > Template > 'Engineering – Meters'*

- Delete the drawing of the person standing at the axis origin by clicking on it and pressing '*Delete*'

2.2 Understanding “Zones” – SketchUp Zones vs.Trnsys3d zones

2.2.1 SketchUp Zones

In SketchUp, the interior walls make up the zones. For example, in the building pictured above, there are no interior walls, so it is modelled as one large rectangular zone. Note that the smaller cube represents an exterior shade and is not a zone.

2.2.2 Trnsys3d Zones

Trnsys3d zones are different from SketchUp zones, particularly because Trnsys3d zones are used to simulate the dynamic flow of energy. An energy model of a building should typically be separated into perimeter and core zones. This is important to separate the effects of infiltration from the perimeter and core, and to correctly account for solar gains into the building.

Trnsys3d zones are restricted to have one airnode associated to it. For special spaces like atria, it may make sense to model a zone with multiple airnodes (see Chapter Frequently Asked Questions FAQ - Atrium and Virtual Surfaces for more details).

convex

concave

It is important to note, that for applying the detailed interior radiation models (solar radiation distribution and/or interior longwave radiation exchange) zones have to be convex volumes.

This means that every surface in the zone should be in the line of sight with all other surfaces of the zone. (no obstructed views)

2.3 Build a single-zone model in Trnsys3d

To use the plug-in as intended, you must have the energy model in mind (NOT the architectural model) from the beginning as you create your SketchUp model.

2.3.1 Automatic Prompt to select pre-made zone template

Upon launching Google SketchUp after the Trnsys3d plugin has been installed, you will be prompted to choose a template for your 3D model. This template contains pre-defined information for your *.b18 file for schedules, heating, cooling, ventilation, infiltration, internal gains and daylight. If you don't want to use a predefined template, choose NewFileTemplate.idf.

Choose German > 1_apartment_basedon_SIA2024.idf and click Open.

For the German library, these zone templates according to SIA 2024 are available:

1. Apartment
 - Living/bedroom
 - kitchen
2. hotel
 - hotel room
 - reception
3. office
 - office
 - office
 - meeting
 - reception
4. School
 - classroom
 - staffroom
 - library
 - lecturehall
 - specialroom
5. Supermarket
 - commercial
6. Restaurant
 - restaurant
 - kitchen

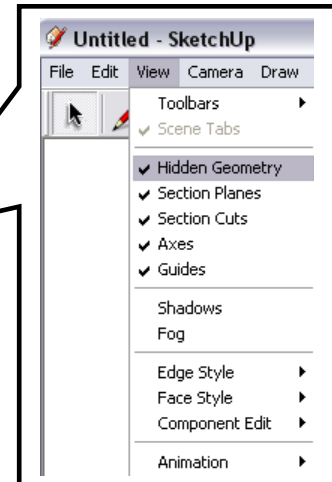

2.3.2 Create a Trnsys3d Zone

Create a new Trnsys3d zone by choosing Plugins > Trnsys3d > New Zone Tool  from the main menu. A small, blue cross-hair will appear at the tip of the cursor arrow. Hover over the axis origin until a small yellow dot appears and click. This will place a blue box on the screen, which represents the Trnsys3d zone. If the blue box is not visible, try changing the view to fit the object by going to Camera > Zoom Extents from the main SketchUp menu. Now you can zoom in and out with the mouse wheel to fit the object in the window as desired.

Note that by clicking on the screen outside of the blue box, the object will disappear from view. This is normal. Turn on hidden geometry (Go to View > Hidden Geometry from the main menu) and a small gray cross-hair will be visible at the opposite corner of the box.

This cross hair allows the user to find the Trnsys3d zone more easily. Note that if you click on the gray cross-hair, the Trnsys3d zone is outlined in blue again.

Double click on the small cross-hair, which is now visible with hidden geometry turned on. The blue outline of the Trnsys3d zone should be replaced with a slightly larger box with a broken, black outline. This 'activates' the Trnsys3d zone. Note that in order to modify the Trnsys3d geometry the Trnsys3d zone MUST be 'activated' (outlined with the broken black line). Alternative to clicking on the crosshair, double click inside the blue box.

This is what separates the Trnsys3d geometry from SketchUp geometry. Any object drawn in a 'non activated' Trnsys3d zone is only SketchUp geometry and will not be written out to the Trnsys3d IDF file.

It is VERY important to make sure the zone is activated before you start creating geometry

2.3.3 Modifying Geometry within the Trnsys3d zone

Make sure that the Trnsys3d zone is still 'active' (outlined with the broken black line). Then create the floor for the model by going to *Draw -> Rectangle*  from the main menu. Start the rectangle at the axis origin by clicking on the origin. Next designate the size of the rectangle by typing '12, 4' and pressing enter (you can see the numbers being input in the lower right hand corner of the screen, the comma between the numbers is operating system language dependent and can also be ;,.). This will create a 12m by 4m floor.

Note the gray color of the floor. This color is automatically generated by Trnsys3d and designates this surface as a floor in Trnsys3d. Similarly, the walls and roof will be colored accordingly, in the next few steps.

Next 'pull' the rectangle up to create a rectangular prism. Make sure that the Trnsys3d zone is still 'active' (outlined with the broken black line). Choose *Tools > Push/Pull* from the main menu. Hover over the rectangle until small blue dots appear on the floor surface and click ONCE with the mouse. The tool will 'grab' the rectangle surface. Move the mouse up and down to see how the tool works. Move the mouse slightly up (so that the rectangle is projecting towards the top of the screen), type '4', and press enter. This will 'pull' the rectangle up to create a 4m tall prism.

Saving the IDF File

It is crucial to save the IDF file early and often. The IDF file is separate from the SketchUp file and saving the SketchUp file will not preserve the IDF information. To save the IDF file, choose Plugins > Trnsys3d > Save from the main menu . If it is the first time you are saving the file a dialog box will prompt you for a location and name.

2.3.4 Creating fenestration objects

Trnsys3d can also be used to generate fenestration objects. Make sure that your Trnsys3d zone is still 'active' (outlined with the broken black line). Use the tape measure tool to create a 1m offset guides from the corner of the wall. *Select Tools > Tape Measure*  and click once on the lower right-hand corner. Hover to a point above the corner, type in '1' and press enter. A small black crosshair will appear. Using the tape measure tool again, click once on the new crosshair and hover to a point left of it, type in '1' and press enter. A dotted vertical guide and another crosshair will now appear on the wall surface.

Now, select *Draw > Rectangle* and click once on the crosshair located on the wall surface. Type in '6,2' and press enter. Note that as long as the rectangle is completely contained within the wall surface, Trnsys3d will recognize it as a window and automatically color it a transparent blue. A skylight is created the same way as a

window, but the rectangle is drawn on a roof instead of a wall. The guidelines can be removed by going to *Edit > Delete Guides*. This will also remove the hidden geometry.

2.3.5 Create external shading objects

Trnsys3d can be used to create shading objects, including overhangs and detached shading objects to represent other buildings. Select *Plugins > Trnsys3d > New Shading Group Tool* , which is very similar to the new zone tool. For this example, place the new shading group at the axis origin. Just like the new zone tool, in order to edit the shading group geometry you must make the group 'active'. To do this, press enter while the shading group geometry is highlighted blue, or double click on the small gray cross-hair that was created when you placed the new shading group. When the shading group is 'active' you should see the rest of the model become lighter.

Use the rectangle tool to create the footprint of a detached shading object. Click the origin once and move the mouse so that the footprint is previewed in the correct quadrant. Type in '4,4', which will create a floor surface of 4m by 4m. (Attention: if your language settings are using "," as the decimal separator, you will have to type "4;4" instead.) Notice that the grey dotted box extends itself to include the floor surface.

Similar to creating a new zone, use the Push/Pull tool  to 'pull' the shading surface up to 4m.

2.3.6 Using the Outliner Window

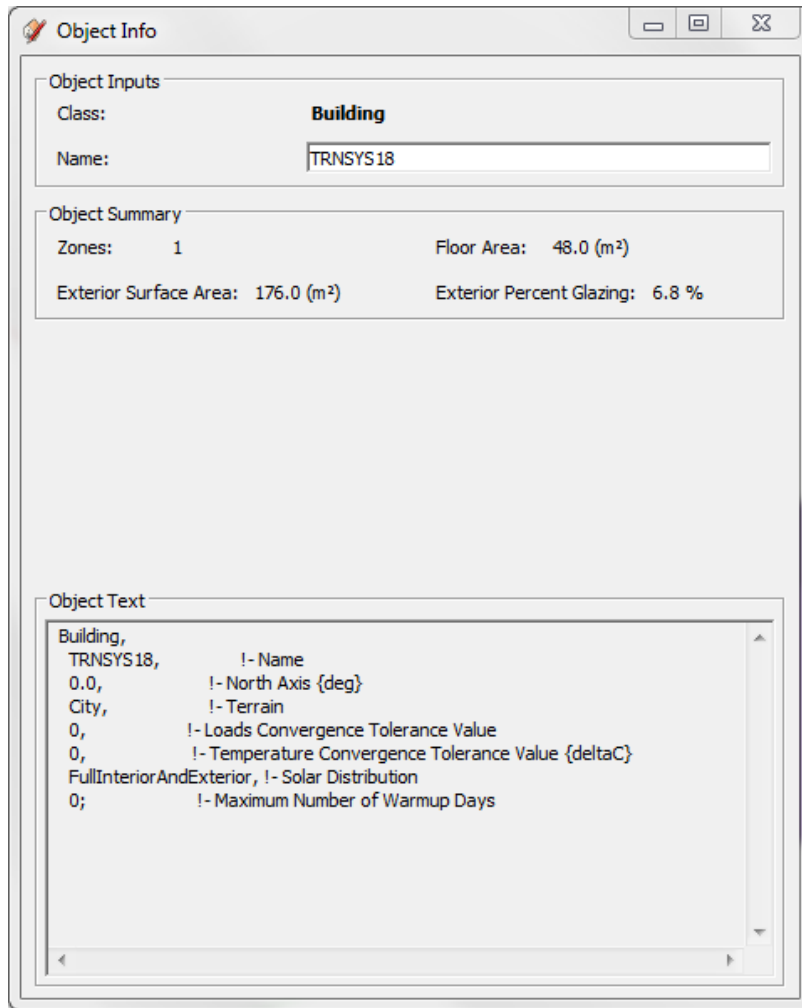

We will now use the outliner window to review the zones that we have created. To access the outliner window from the main menu choose *Window > Outliner* .

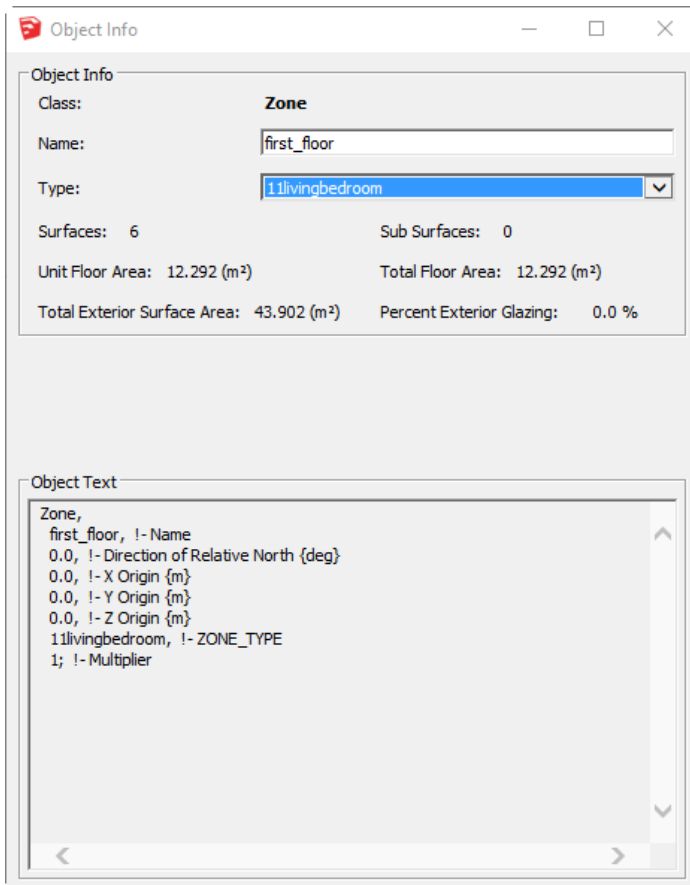

You can use the outliner window to select the Trnsys3d objects by clicking on them. Double clicking on an object in the outliner window will 'activate' the object. You should have one Trnsys3d shading group and one Trnsys3d zone with a random six-digit alphanumeric name. If you have any additional objects placed on accident select them in the outliner window and delete them.

2.3.7 Using the Object Info Tool

Trnsys3d also has the ability to modify the Trnsys3d object information. Choose *Plugins > Trnsys3d > Object Info* . The class type will change as objects are selected on the screen. If nothing is selected, the class type is 'Building'. Change the name of the building to 'TRNSYS18'

Click on the zone in the main SketchUp drawing area and you will see the class type change to 'Zone' in the object info window. Change the Zone name from the default six-digit alphanumeric zone name to 'First_Floor' (!!!NOTE: No Spaces!!!) and press TAB on your keyboard to confirm. Select the Zone Type template '11livingbedroom' from the drop-down for 'Type'.

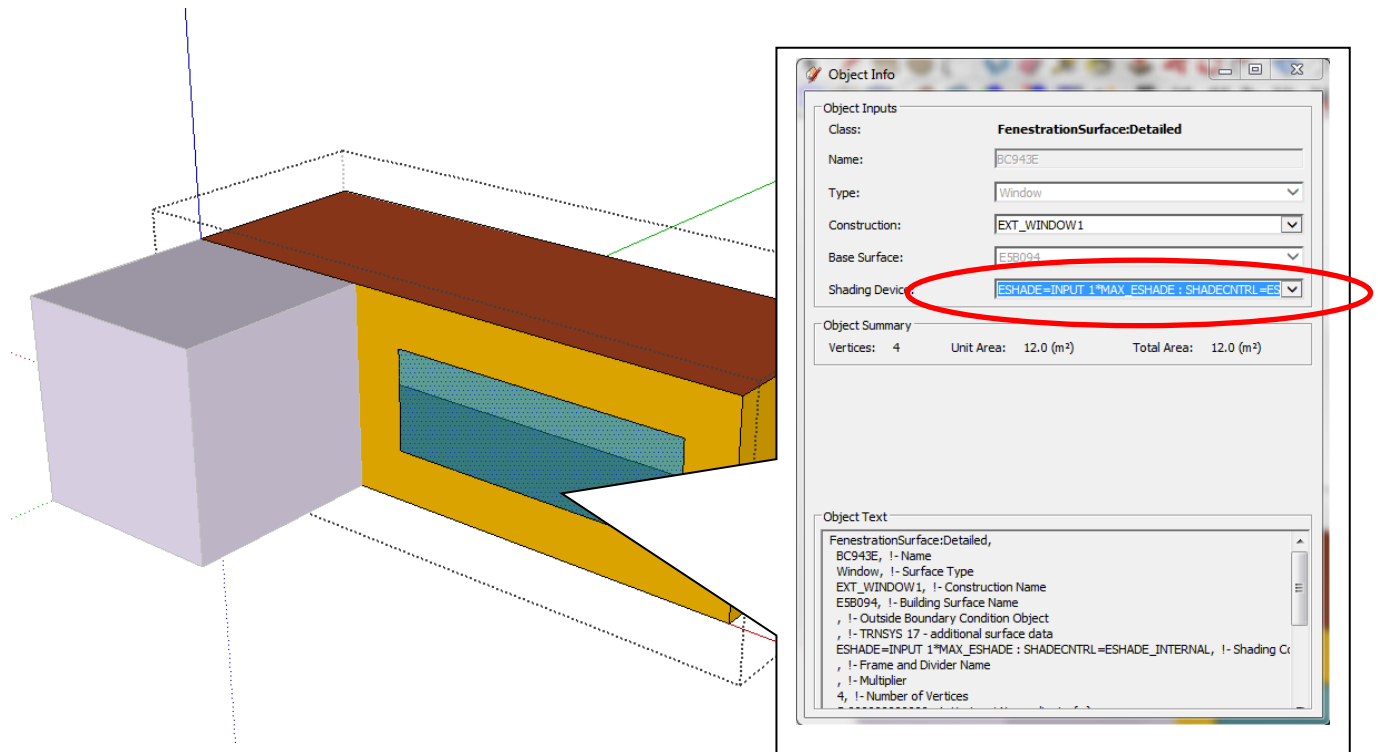

Open the outliner window again; notice that the Trnsys3d zone name has changed.

With the object info window still open double click on 'First Floor' in the SketchUp model to 'activate' the zone. Notice how the object info changes as you select a wall, roof, or window (note characteristics like surface name, type, construction, zone, outside boundary conditions, and the ground view factor). You can change the surface type, the construction, and outside boundary condition for each surface. Toggle between surfaces by clicking on them on the main SketchUp window. You cannot change the surface name, as it will be automatically changed later on.

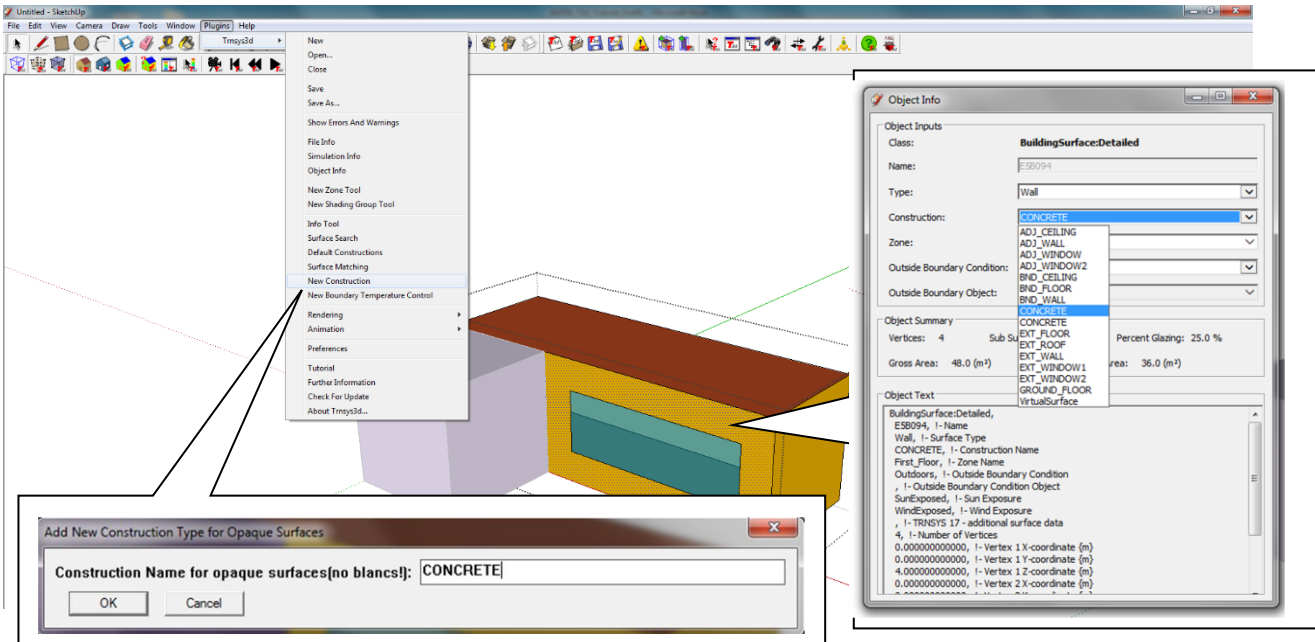

2.3.8 Movable shading for windows

Windows in TRNSYS 18 can have an automatic internal shading calculation depending to user-defined set points. For this reason in the Object Info of Trnsys3d for windows there is a new drop down called shading device. Here one can define if the window will have an internal or external shading device. The set points can later on be adapted in the TRNBUILD window type manager.

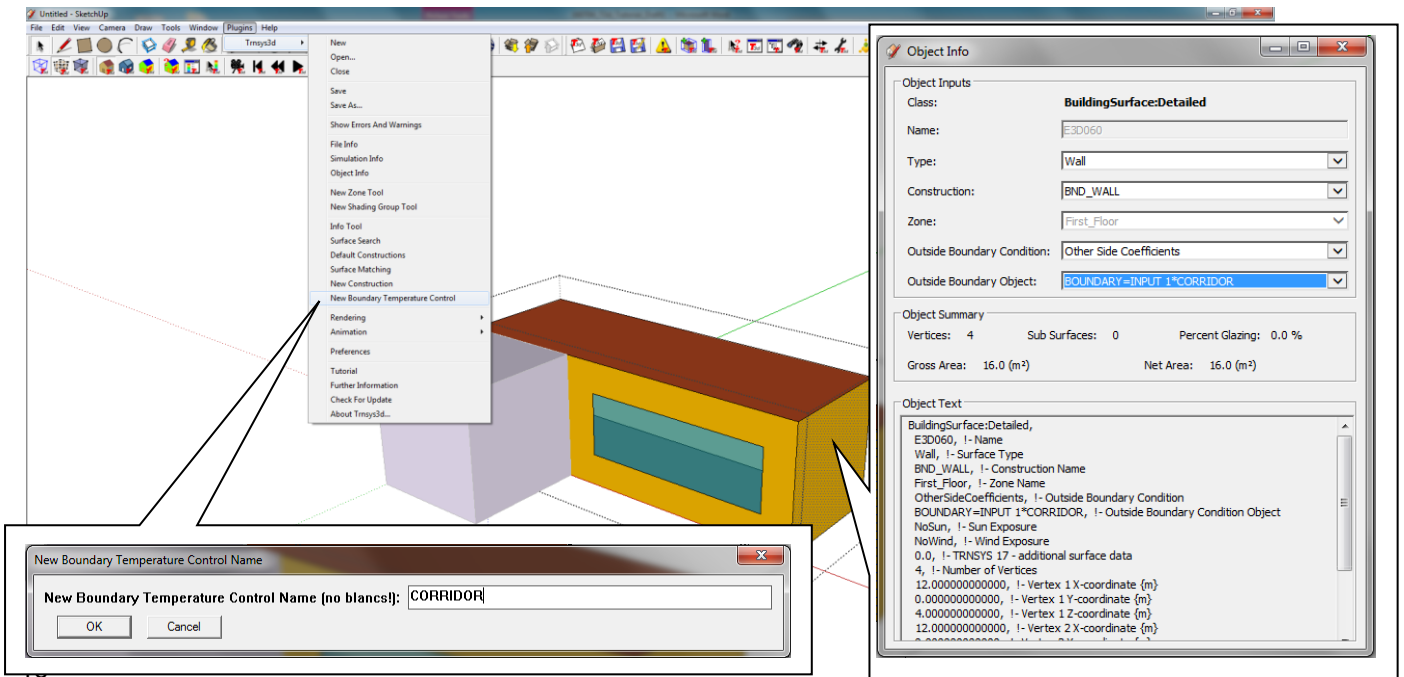

2.3.9 User-defined wall constructions

The option to define a new construction can be accessed through the SketchUp *menu > Plugins > Trnsys3d > New Construction*. This allows defining user-specific names for constructions that can be afterwards selected by the Object Info Window. The detailed wall construction including the layers and their thicknesses will have to be done after the import in TRNBUILD.

2.3.10 User-defined Boundary Temperatures

The option to define a new boundary temperature control can be accessed through the SketchUp *menu > Plugins > Trnsys3d > New Boundary Temperature Control*. This allows defining user-specific INPUT variables for a boundary temperature that can be afterwards selected by the Object Info Window. Make sure to change the Construction to 'BND_WALL', Outside Boundary Condition to 'Other Side Coefficients', and Outside Boundary Object to 'BOUNDARY=INPUT 1*CORRIDOR'.

2.4 Add a second zone in Trnsys3d

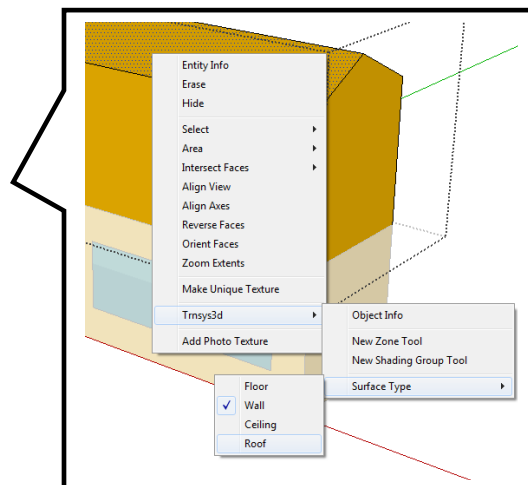

Create the second floor of the example model by creating a new Trnsys3d zone and repeating the previous steps, but 'pull' this floor to 5m instead of 4m. To create a sloped roof, portions of the rectangular prism will be 'sliced' off. Using the tape measure tool, place a crosshair guide 1m below the upper corner, as shown below. Then select *Draw > Line*  and draw a line from the crosshair to the midpoint of the top edge. (The midpoint shows up in blue when you hover over it.) Draw another line connecting the midpoint to the edge opposite of the one with the crosshair, outlining the shape of the sloped roof.

Select *Tools > Push/Pull*, hover over a triangle until the blue dots appear and click once inside the triangle. Move the mouse towards the other end of the prism until the cut follows through the entire length of the prism and click to complete the 'slicing' (the cursor will snap to a triangle at the other end.) Repeat for the other triangle.

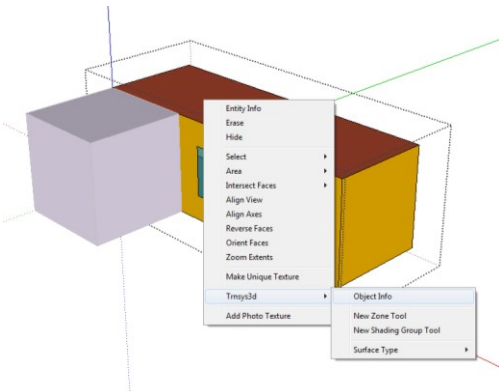

Note that the sloped roof you just created is now the same color as the walls. To re-assign the surface type in Trnsys3d, right-click on the surface make the selections as shown below to finally choose 'Roof' for each sloped surface. Repeat previous steps to rename this zone as "Second Floor"

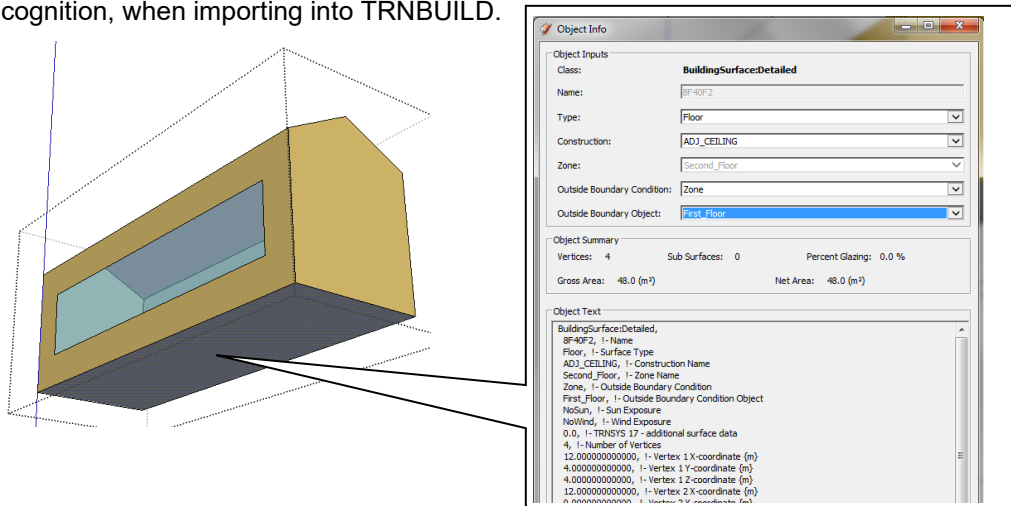

Finally, the interzonal adjacencies must be considered. The mating surfaces between the First Floor and Second Floor must be linked together. Open *Window > Outliner*, and right click on the Second Floor to 'Hide' it. If *View > Hidden Geometry*  is checked, then the second floor will appear hatched. You must uncheck it to hide it.

Next, double click the First Floor zone to 'activate' it. Right Click on the roof of the first zone and select *Trnsys3d > Object Info*. Change the Type to "Ceiling" and construction to "ADJ_CEILING". The outside boundary condition should be "Zone" and the outside boundary object is "Second Floor."

Right click on the Second Floor in the Outliner to unhide it. Repeat the same steps above to hide the First Floor and reassign the floor of the Second Floor correctly. See the Object Info entries below. Note that although the type of the Second floor is 'Floor', the construction must match the First Floor (ADJ_CEILING). This is critical for adjacency recognition, when importing into TRNBUILD.

Surface TYPE definition: VirtualSurface

Note that the surface type definition "VirtualSurface" is a special one which is designed to be used for generating a zone with multiple airnodes. It is NOT representing a heat transfer surface in the building model.

See Chapter *Useful Tips/ Frequently Asked Questions FAQ* -

2.4.1 Matching Surfaces

A method for automatic surfaces matching can be accessed through the SketchUp Trnsys3d menu toolbar. Click on the surface matching icon  to start matching walls, roofs and floors. A window will pop up that gives you different options like matching/unmatching surfaces or also to show the last reported matching information.

Depending on the size of the models and the select geometry for matching surfaces this can be a slow process. Note that this method requires several key assumptions.

First, in order to match two surfaces the methods requires that they both have same number of vertices and that the vertices exactly line up. This can most easily be accomplished using the snap functionality of the SketchUp drawing tool.

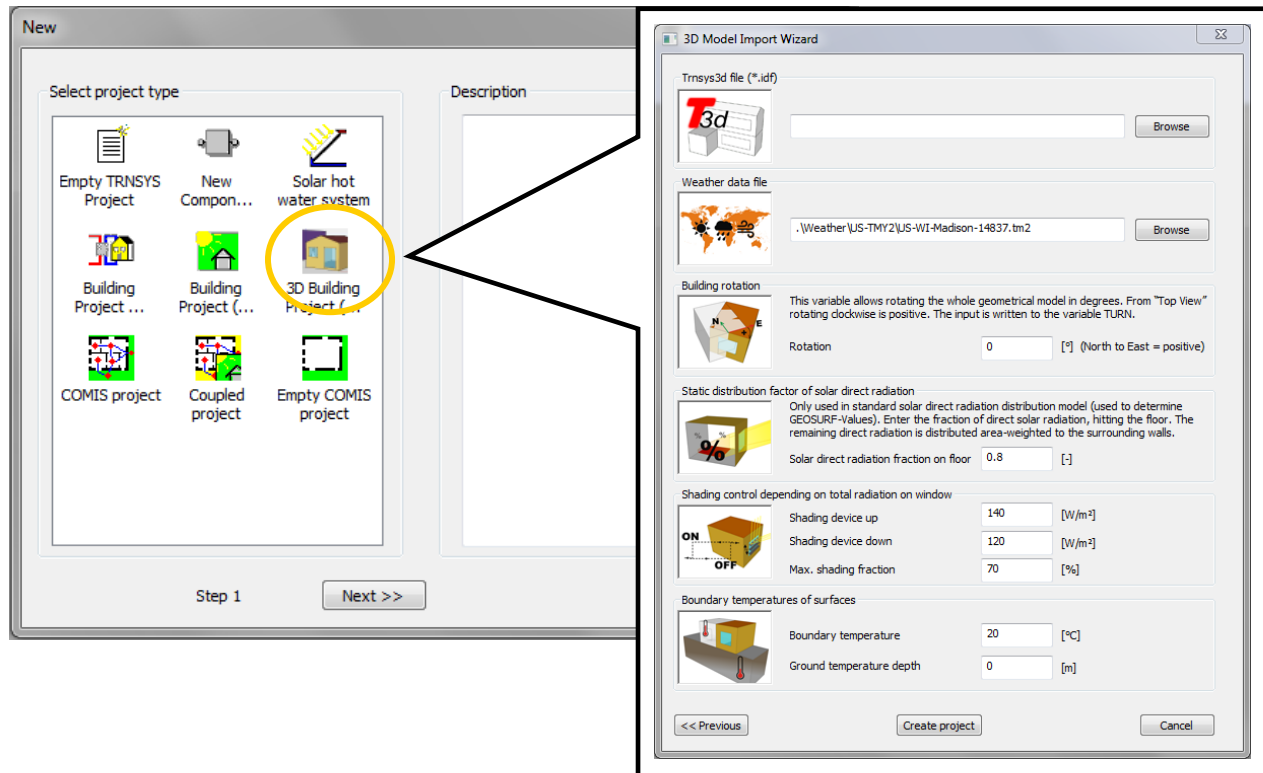

Secondly, construction names of the matched surfaces will be changed to (for each corresponding surface or sub surface type): "ADJ_CEILING" and "ADJ_WALL" if construction objects of those names appear in the current idf file. If construction objects with the assumed names are not found, then the construction of the matched surface will not be changed.

3 Import 3D geometry into Trnsys Simulation studio and TrnBuild

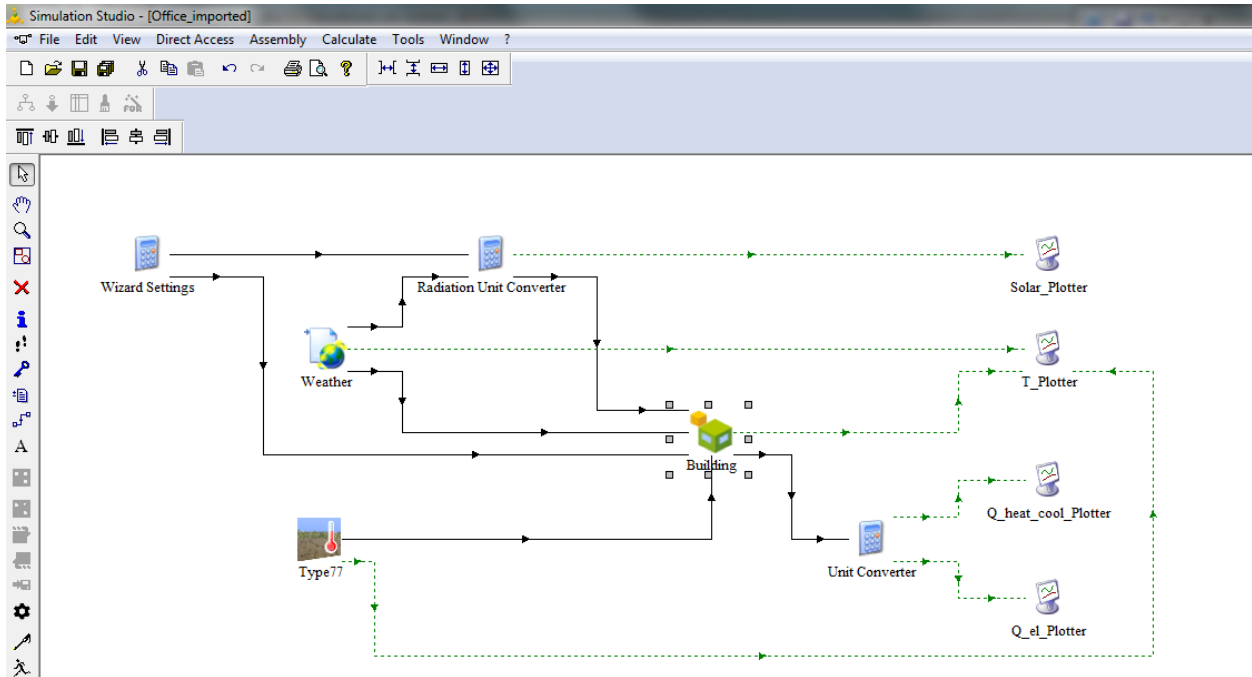

3.1 Import IDF File into Simulation Studio with the Wizard

The TRNSYS18 Simulation Studio offers the opportunity to automatically set up a simulation by importing the *.idf file with the 3D-Building Wizard. After opening the Simulation Studio, select 'New Project' in the menu and the 3D-Building Project Wizard can be chosen. The Wizard prompts you for the location of your *.idf file, the location of the weather data file, (Note: The wizard requires a *.tm2 data format, you can change the reader and assign a different weather file of any other format later on) the building rotation, the static distribution factor of solar direct radiation (typical range from 0.6-0.8), shading controls for exterior shades and boundary temperatures of the ground and any adjacent spaces.

A great advantage of the 3D-Building Wizard is that all orientations of the Building are linked automatically. This reduces errors and time used to link this information manually.

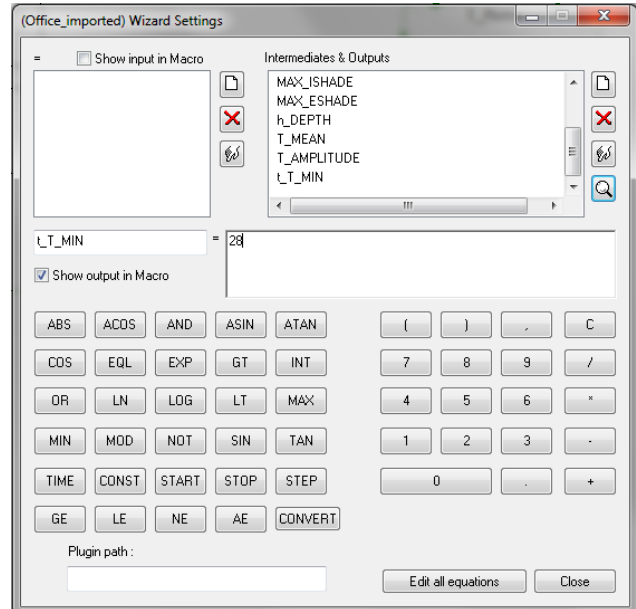

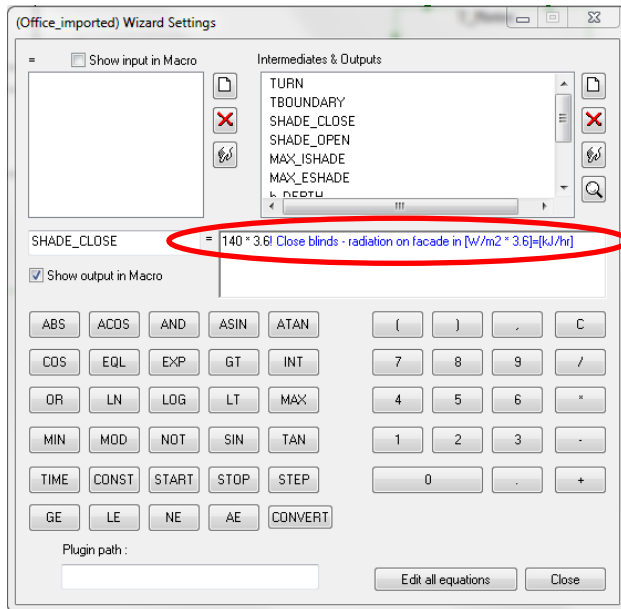

The main reason for importing the 3D geometry into Simulation Studio is to use the Studio Wizard to generate the *.b18 and *.tpf files, which happens after you create the project with the Wizard. The *.dck is generated when you click Calculate > Create Input File. The inputs for the model in Simulation studio are populated with information from the IDF template that was selected during the launch of SketchUp.

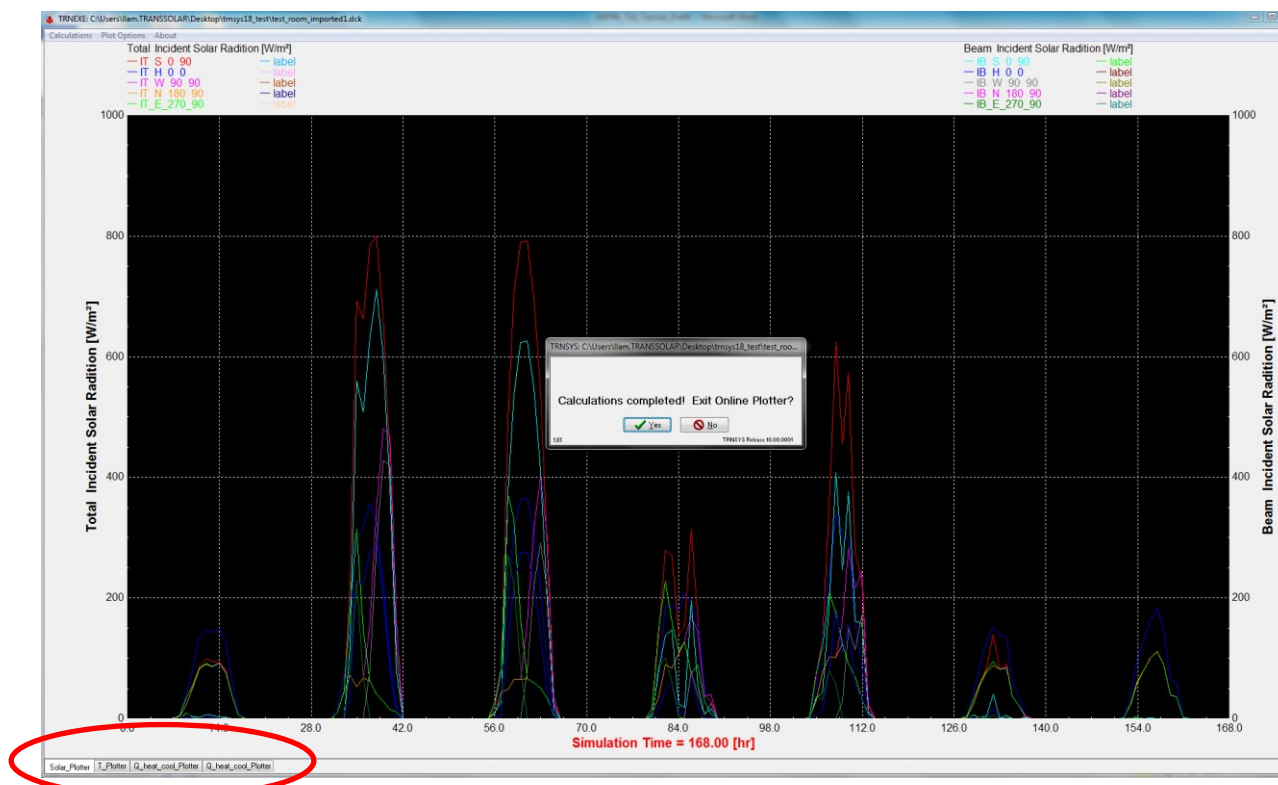

Select *File > Save* to save the Studio project.

The Wizard creates a 3D model with default settings which can be found under “*Wizard Settings*”. Double click the Wizard Settings icon to see input variables. Double click each input variable to see default assignments. It is possible, for example, to adjust the control for SHADE_CLOSE, directly in the circled cell below.

For ground-adjacent models, it is important to define ‘t_T_min’, as highlighted in the image to the right, below. This variable equals the ‘coldest day’, in this example, 28 days from the start of the new year. Identify the coldest day for your climate and adjust t_T_min as necessary.

For a first run, click *Calculate > Run Simulation*, which will launch Trnsys18 and by default it will run for a single week. Trnsys18 will prompt you to “Exit the Online Plotter” upon completion of the simulation. Click “No” for the purposes of this tutorial.

By default there are 4 tabs along the bottom of the Online Plotter, showing outputs for solar radiation, temperatures, heating and cooling power, and electricity consumption of interior loads. Hold down shift and hover mouse in plotter area to see instantaneous values. User-defined outputs can be added, see next sections.

The directory where the Studio file is saved should now be populated with *.b18 and *.dck files.

3.2 Import IDF File directly into TRNBuild

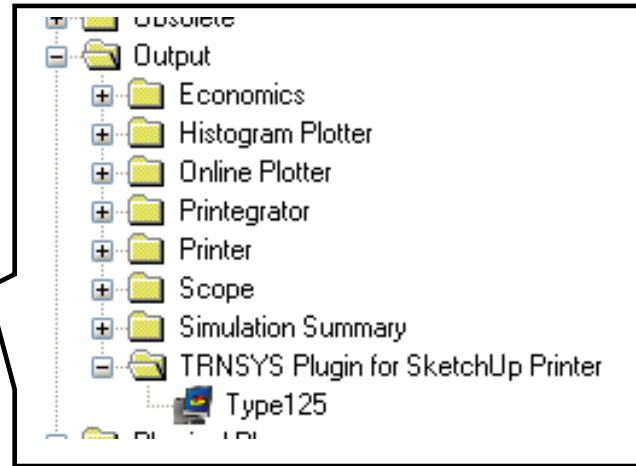

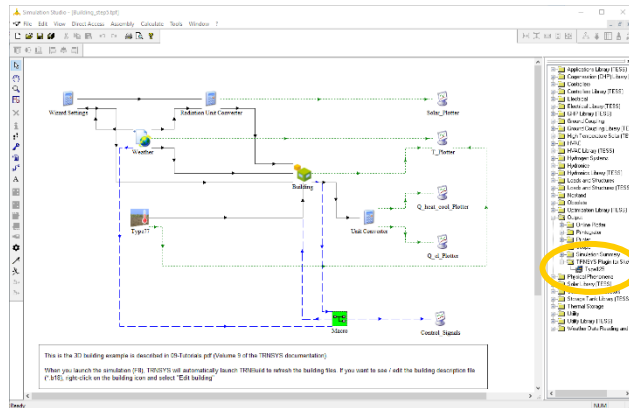

It is also possible to import 3D geometry into TRNBuild, however this approach only generates the *.b18 file and is only appropriate when you have an existing *.dck file. This alternative workflow where the *.dck file is created from scratch, is not covered in this tutorial. See the part 9 of the TRNSYS Documentation for details on this.

3.3 Further Information

For further information on how to add further data such as materials, controls, internal heat gains, HVAC equipment and systems, etc. using TRNBuild and run simulations, please see the TRNSYS Tutorials at c:\TRNSYS18\Documentation\09-Tutorials.pdf (Chapter 9.3.2.4. Step 3 - Modification of the building description (TRNBuild)) and the building model manual c:\TRNSYS18\Documentation\05-MultizoneBuilding.pdf.

4 Viewing Results in Trnsys3d

Trnsys3d can be used to view Trnsys3d results. But first, the Trnsys3d requires results to be printed from the Trnsys3d Printer (Type 125), which is retrieved from the Direct Access Toolbar in the TRNSYS Simulation Studio.

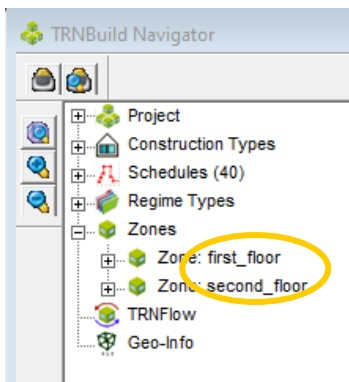

The Trnsys3d Printer will generate *.eso files that can be read by the Trnsys3d plugin to visualize results. The Trnsys3d printer can be configured in two different ways.

- 1) The SurfacesID's (corresponding to the ID's in TRNBUILD) are required as initial values.

SurfNo.	ITvde	Area	Category
8	GROUND_FLOOR	48.00	BOUNDARY
9	EXT_WALL	16.00	EXTERNAL S_0_90
10	ADJ_CEILING	48.00	ADJACENT OG
11	EXT_WALL	16.00	EXTERNAL E_270_90
12	EXT_WALL	32.00	EXTERNAL S_0_90
13	EXT_WALL	16.00	EXTERNAL W_90_90
14	EXT_WALL	48.00	EXTERNAL N_180_90

Parameter	Input	Name	Value	Unit	More	Macro
1	Input-1		5	any	More...	✓
2	Input-2		9	any	More...	✓
3	Input-3		10	any	More...	✓
4	Input-4		11	any	More...	✓
5	Input-5		12	any	More...	✓
6	Input-6		13	any	More...	✓
7	Input-7		14	any	More...	✓

- 2) The airnode names (corresponding to the names in TRNBUILD but with **CAPITAL LETTERS**!) are required as initial value. Initial value has to be defined as **variable name**.

Parameter	Input	Name	Value	Unit	More	Macro
1	Input-1		FIRST_FLOOR	variable name	More...	✓
2	Input-2		SECOND_FLOOR	variable name	More...	✓

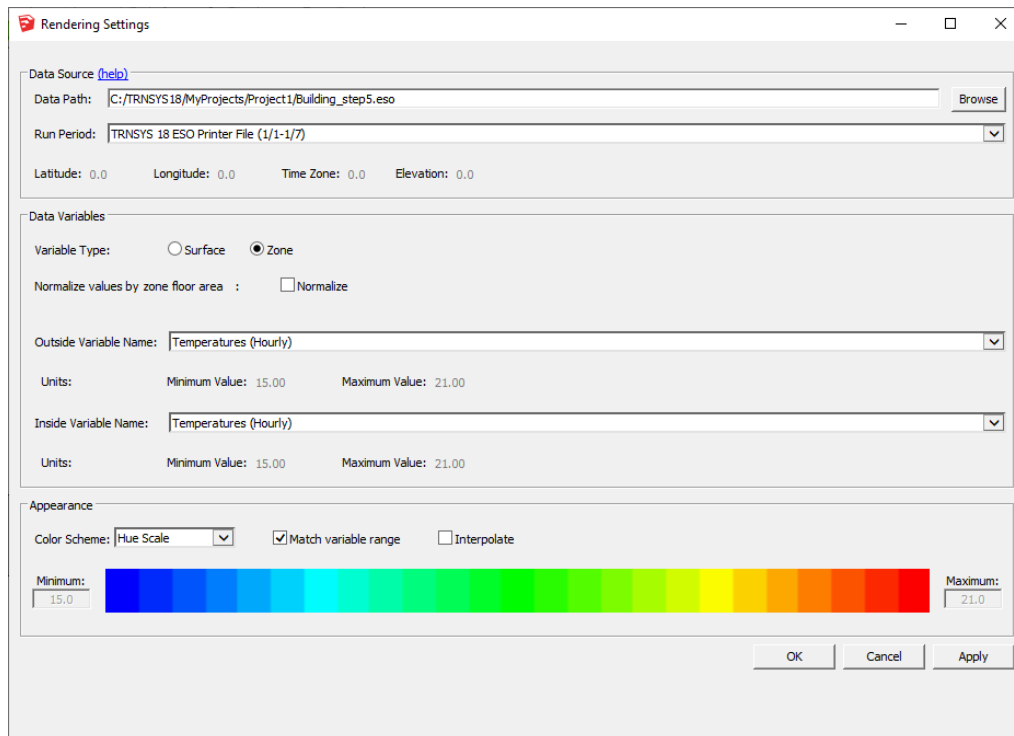

The information from the surfaces and airnodes can now be linked to Type125.

Because the information in the data file will be interpreted by SketchUp and laid over the wire frame model of the building it is important that you include only one kind of output information (so-called NTYPE) in each file produced by Type125. Thus, one instance of Type125 might be used to print air temperatures, another one for heating loads and a third for surface temperatures.

Do not, however include data for both temperature and relative humidity in the same instance of Type125.

After linking the surfaces or airnodes outputs, it is recommended to open the building model in TRNBuild by selecting “*Edit Building*” and export the model as a Trnsys3d file *****_B18.idf** to ensure that all changes made in TRNBuild are included. The *****_B18.idf** model can be reloaded into Trnsys3d. First, go to the main SketchUp menu and chose *Plugins > Trnsys3d > Renderings > Settings* . This will open the rendering settings dialog box.

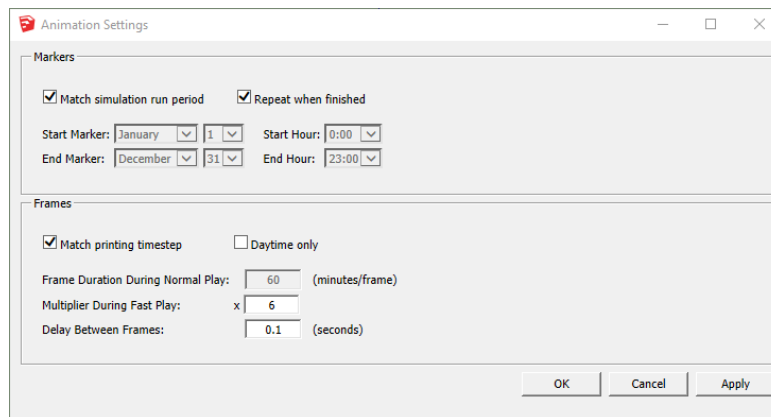

Set the data path by browsing to the directory where you saved your IDF file. There should now be an ESO file generated by the Simulation Studio during the simulation. Choose the ESO file for the data path. The run period will automatically be filled once the ESO file is selected. Set the rest of the Rendering settings as shown above and click ‘OK’. The dialog box will close and nothing will appear to change. We now need to set Trnsys3d to render by data value instead of by surface class. To do this go to the main SketchUp menu and chose *Plugins > Trnsys3d > Renderings > By Data Value* .

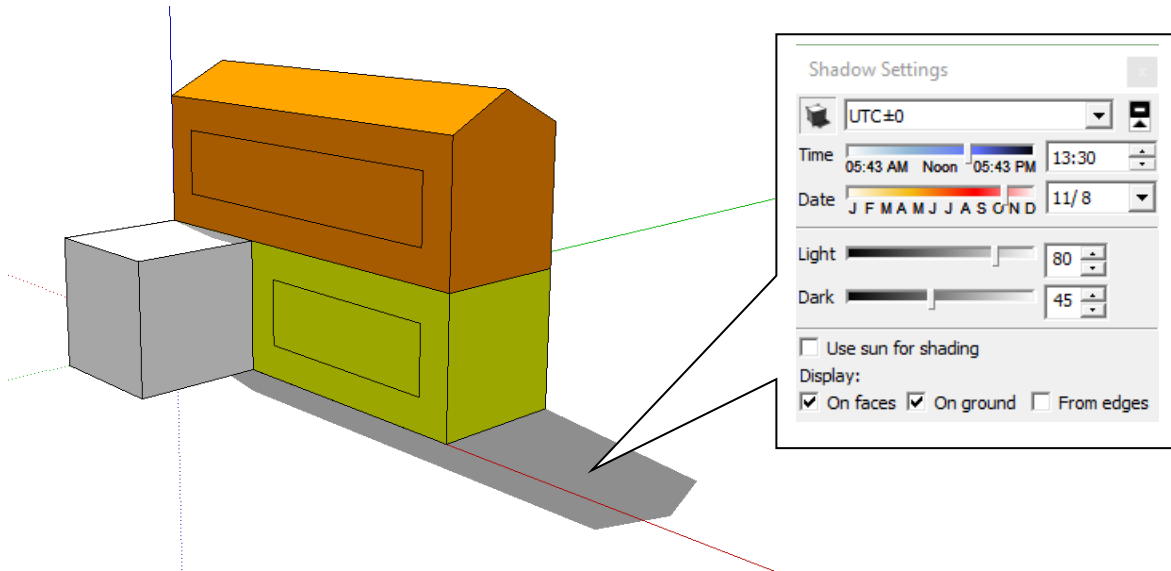

If any portion of model appears white, it indicates that no data results are available from the TRNSYS simulation for the selected date for that zone. The model should be coloured based on the airnode air temperature, as shown below.

Try matching the simulation run period in Trnsys3d with the Trnsys Simulation Studio results by setting it to the first week of January. In the SketchUp main menu, choose *Plugins > Trnsys3d > Animation > Settings*. This will open the Animation Settings dialog box.

Check the 'Match simulation run period' and the 'Repeat when finished' checkboxes as shown above and hit 'OK'. Lastly we need to reset the time to the beginning of the run period. In the SketchUp main menu, chose *Plugins > Trnsys3d -> Animation -> Reverse to Marker*. Make sure that the bottom left corner of the screen indicates January 01. If it says January 08, choose *Plugins > Trnsys3d > Animation > Reverse to Marker* again. Now the bottom left corner of the screen should say January 01. Also, turn on shadows to see the position of the sun by going to *View -> Shadows* from the main SketchUp Window. Note for displaying shadows correctly, the time zone has to be set to building location. (The geo-location of your model can be set in *Window > Model Info > geo-location*)

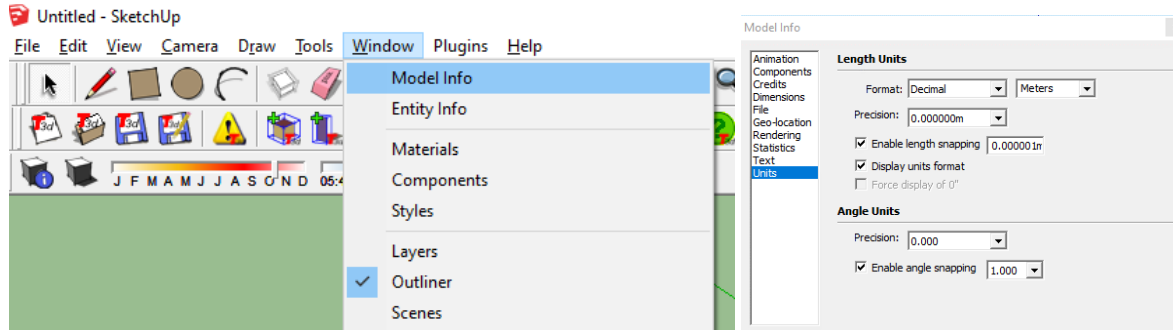

Now that we have reset the time and have shadows on, we are finally ready to view the animation. To begin the animations go to the SketchUp main menu and chose *Plugins > Trnsys3d > Animation > Play*. At the bottom left of the screen you will see the time and date as the animation progresses. Notice that the zones are all slightly different colors, meaning that their temperature is different because of their construction, occupation,.....

While the simulation is running we can view the temperature scale by going to the main SketchUp menu and chose *Plugins > Trnsys3d > Renderings > Color Scale* . Stop the animation the same way you started it, by going to the SketchUp main menu and chose *Plugins > Trnsys3d > Animation > Play* . Once the date passes the end of our run period the model will turn white because there is no data for it to display. The animation can begin from the beginning by first halting playback by going to the SketchUp main menu and choose *Plugins > Trnsys3d > Animation > Play* and then resetting the time by going to the SketchUp main menu and chose *Plugins > Trnsys3d > Animation > Reverse to Marker*.

5 Useful Tips/ Frequently Asked Questions FAQ

5.1 General

- Read the SketchUp documentation.
- Check that unit settings are set to “High” accuracy

- You may encounter difficulties using directories with “ä”, “ö”, “ü”, blanks etc.
- To position vertices with precision or create surfaces with exact dimensions, use the *Measurements* in the lower right corner or use construction lines.

- To draw quickly and accurately, use SketchUp’s snapping capabilities. For example, to match the x-, y-, or z-position of the endpoint of a line, hover the cursor over the endpoint until the tooltip appears. Click ONCE. As you move the mouse, SketchUp will let you know when you are parallel to the reference line. To lock a snapping function along an axis, hold down the shift key while you draw, and the line will appear bold and in the same color as the parallel axis.

5.2 Surfaces

- In Trnsys3d, all building surfaces (walls, floors, etc.) are represented in 3-D coordinates as infinitesimally thin. Zone volume and surface area, which are automatically calculated entities, are derived from those 3-D coordinates. However, you may modify the volume within TRNBuild.
- The construction that you select for each surface determines the thickness for the purposes of the heat transfer calculation, but it does not affect any geometric considerations.
- Typically, the building surfaces are measured from the outside edge of exterior walls, and the centerline for adjacent walls. At the building corners, measuring from the outside edge will overestimate the total mass of the walls, while measuring from the inside edge will underestimate it. It is easier to measure the outside edge from the blueprints, but measuring from the centerline is the more accurate approach. If the walls are especially thick, consider measuring from the centerline of the exterior walls.
- The y-Axis is pointing north. There is no way to change this.
- To add surfaces to a zone, the zone must be 'activated' by double clicking the blue outline. An activated zone will be outlined in a grey dotted line.
- Surfaces have to be drawn with an outward-pointing normal vector! Occasionally when you draw a surface, SketchUp will guess the wrong side to face out. You can tell because the side facing inside is a lighter color than the side facing outside. To correct this, use the SketchUp command *Edit > Face > Reverse Faces*.
- Note that even if you rename your surfaces, they will be replaced with the surface IDs that are generated automatically when importing into TRNBuild.
- Check and set the correct "Type" of all adjacent surfaces (Wall, Floor, Roof, Ceiling).
- Select a "construction" for each surface. Otherwise the surface cannot be imported into TRNBuild correctly. The constructions can be modified within TRNBuild later.
- This shows the translation of "Outside Boundary Conditions" into TRNBuild syntax:
Outdoors => EXTERNAL
Ground => BOUNDARY = INPUT 1*TGROUND
Zone => ADJACENT = zonename
Other Side Coefficients => BOUNDARY
- Adjacent surfaces have to exist twice (once for each zone), but with different normals. Despite 'Type' differences (floor/ceiling, wall/wall, etc), adjacent surfaces must have the same construction for proper syncing within TRNBuild.
- Active slab surfaces should be divided in Trnsys3d (3 partitions for the active slab system are usually sufficient). To create divisions, simply draw a line.

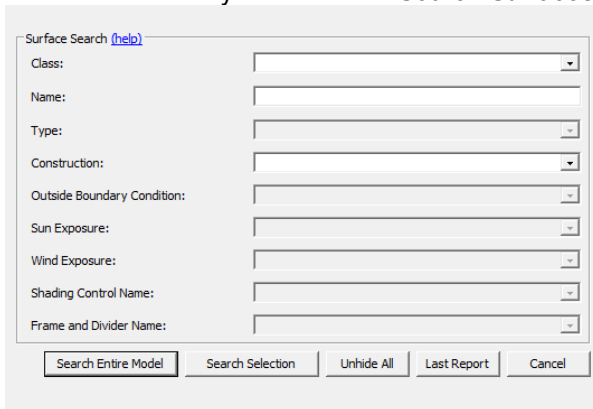

Note, the autosegmentation functionality within TRNBuild can't be used to automatically divide the slab for 3D geometry.

- Check for holes in surfaces! Surfaces with holes cannot be handled by TRNBuild and have to be split.
- Windows are linked to its base surface and should not have more than four vertices.
- Windows are usually drawn to the measurements of the window opening in the wall, including the size of the transparent glazing and the opaque frame. The frame is taken into account by setting a frame fraction and some properties in TRNBuild. Alternatively, you can model the window frame as a opaque surface and set the frame fraction of the window to `FFRAME = 0`.

- If you copy and paste surfaces make sure that the destination zone is active. You can copy surfaces from one Trnsys3d file into another, but sub-surfaces (windows) will not be recognized. Review Trnsys3d surface entities by checking “Object info”. Windows can be copied in a second step onto the base surface.

5.3 Troubleshooting

- Use “Wireframe View” or “View Model in X-Ray Mode”  and the matching surface report option for checking if adjacent surfaces are mated and if the total number of the matched surfaces is equivalent to the available adjacent surfaces.
- If a certain construction element is causing problems during the surface matching or importing procedure then these can be easily found in the “Search Surfaces”  option.

- Type in the name of the surface or select an option by the active scroll-down menus. By clicking on “Search...” automatically all not-fitting elements will be hidden. Select “Unhide All” to show the whole model again.
- Check the number of surfaces and sub-surfaces in each zone.
- Check the boundary conditions of the model by “Render By Boundary Conditions” that highlights the geometry of a certain color syntax .

- Always OPEN and SAVE the file within the Plug-in functionality.
- Before closing the IDF file in Trnsys3d, save it and open it in another Sketchup file to check that everything works accordingly.
- Before closing the IDF file in Trnsys3d, translate the IDF file into B18 and check if everything is translated and makes sense.

5.4 Trnsys3d zones

- Give Trnsys3d zones “meaningful” names. **No blanks** are allowed!!
- Trnsys3d zones have to be closed volumes, otherwise the volume calculation by the import in TRNBuild goes wrong.
- To use the detailed interior radiation mode (shortwave and/or longwave radiation), the zones must be convex polyhedrons.

Use the Outliner window (Window/Outliner) to view a list of all of your zone groups and shading groups. Groups can be selected by clicking items in the outline. Groups can be opened for editing by double-clicking items in the outline.

- Use the command *View > Component Edit > Hide Rest Of Model* to hide all other groups (and the rest of the model) when you are editing a group. When used with the Outliner, this command helps you get to zones that are buried in the core of a building.

5.5 Atrium and Virtual Surfaces

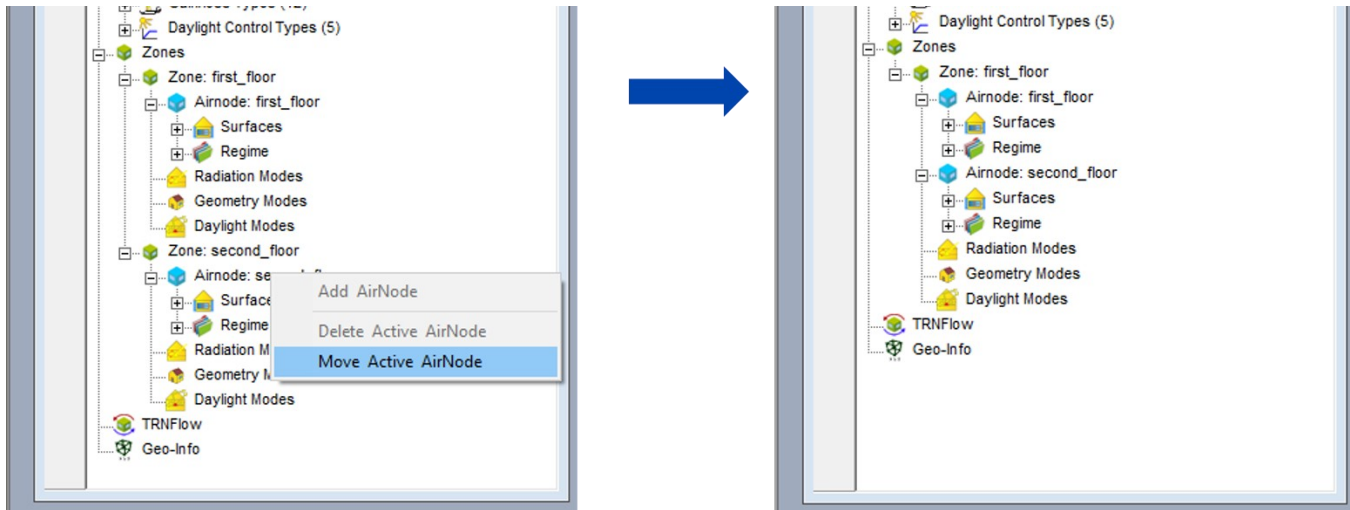

In general, as in trnsys3d a building zone consists of one airnode. The simulation of zones with multiple airnodes is an advanced modelling feature. Large volumes like atria are often modelled by a stack of airnodes within one zone. Thereby the top airnode may have a higher temperature as the bottom airnode. The solar radiation entering a zone is distributed to all surfaces of all airnodes of that zone such that the radiation transmitted by the roof glazing of the top airnode may strike the floor surface of the bottom airnode. In addition, all surfaces of all airnodes of a zone are in longwave radiation exchange if the radiation mode longwave detailed is used (see \TRNSYS18\Documentation\05-MultizoneBuilding.pdf section 5.2.7.12).

As Trnsys3d zones are restricted to one airnode, each airnode of the atrium should be defined as a separate Trnsys3d zone. The construction of the adjacent 'surfaces' between the Trnsys3d zones, which do NOT exist in the real world, should be assigned to 'VirtualSurface'. Note that the surface type of the 'VirtualSurface' can be Floor, Ceiling and Wall only.

'VirtualSurfaces' are not considered as heat transfer surface surfaces and are therefore not including in the thermal model after the import into TRNBuild. However, they are needed for ensuring that the Trnsys3d zones are closed volumes. (This is important for a correct volume calculation.) For enabling a correct export from TRNBuild to Trnsys3d the surface information is written in the geometry part of the *.b18 file.

Within TRNbuild you can move air nodes from one zone into another (including the geometric information). This way you can create radiative zones with multiple air nodes. For this, you right-click on the airnode name in the TRNBuild Navigator and select Move Active AirNode.

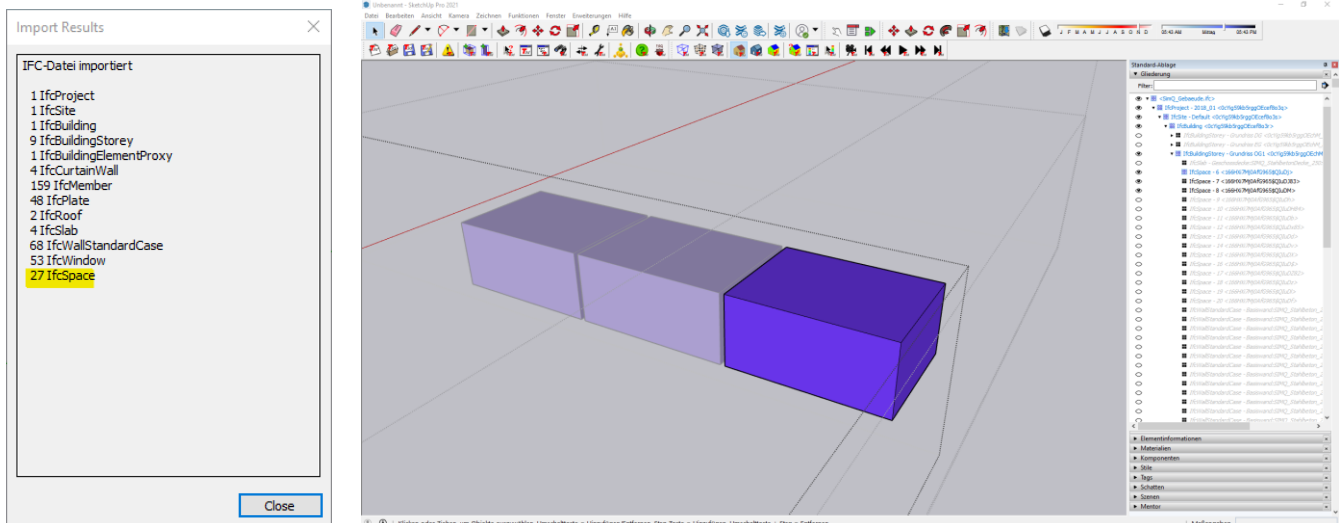

5.6 Importing Geometry from ifc-/dwg-Files to Trnsys3d

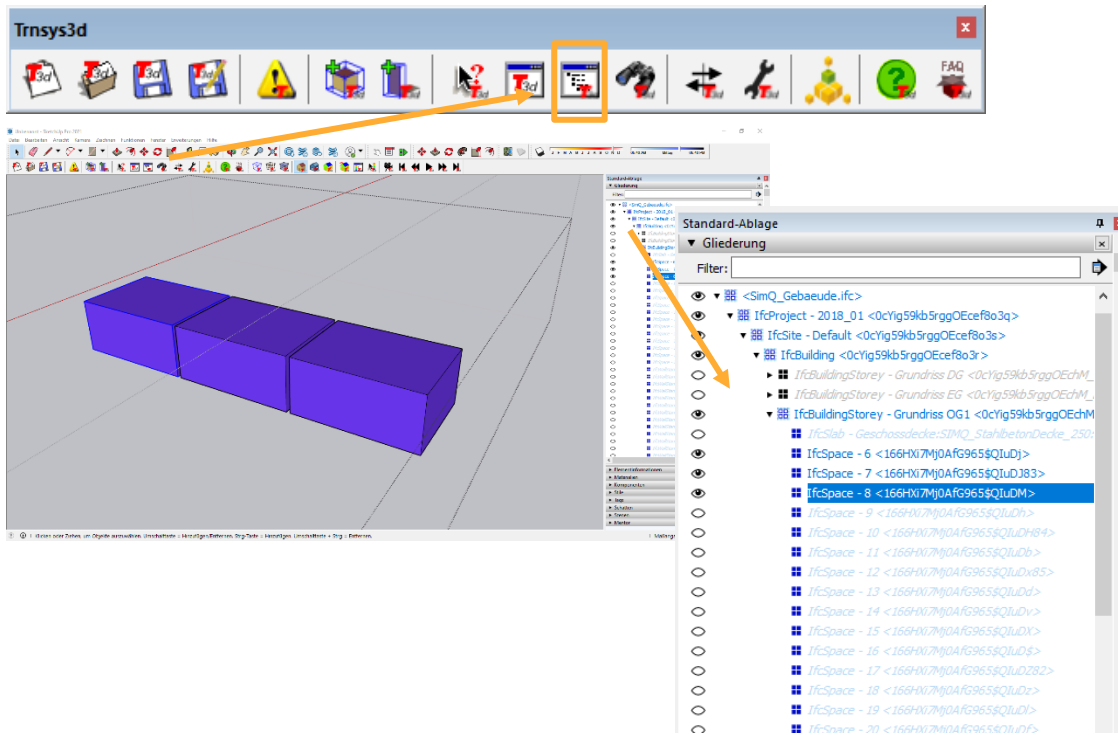

It is possible to copy existing geometry from other files or file formats into a Trnsys3d idf, as long as the geometry is suited for the use in the TRNSYS building model:

- Air volumes have to be closed.
- Boundary surfaces of an air volume have to be presented by planar polygons without holes.
Note: Windows must not be cut out of opaque surfaces
- Boundary surfaces of an air volume should have no thickness (infinitesimally thin).
- For considering thermal conditions of adjacent spaces automatically the boundary surface of both volumes must lie exactly on top of each but with reversed normal vectors (no distance). (see section *Matching Surfaces*)
- Windows should be in separate “group” than the opaque surfaces.

One example of geometry that can be used is ifc-exports that contain ifcSpaces. With the import function of SketchUp, the whole ifc model including the ifc spaces is imported.

- Open the “Show outline window” of Trnsys3d plugin to see the imported data. If you are using ifc-Spaces, or you will find the zone(s) as grouped objects.

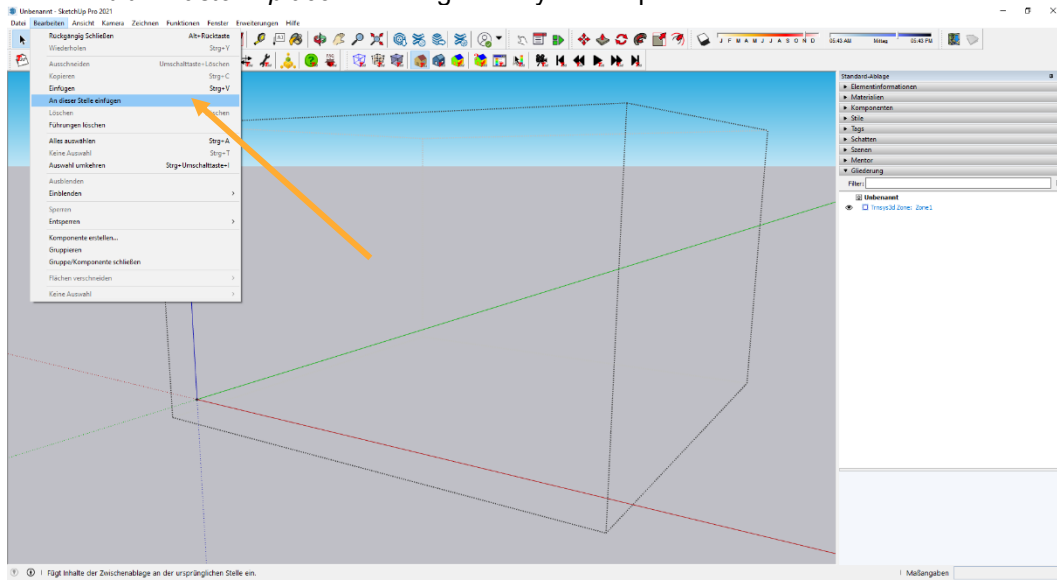

- Copy the surfaces of a zone by highlighting one group and copy it using Ctrl+C or *Edit > Copy*.
- Open another Sketchup window to use the Trnsys3d plugin.(This minimizes error messages and provides a better overview what's already copied into zones)
- Create a new Trnsys3d zone and assign a short name (no blanks).

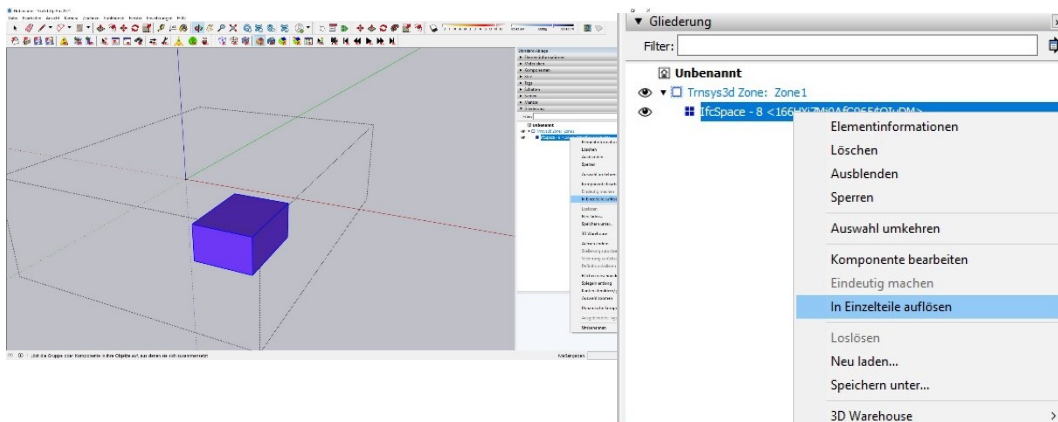

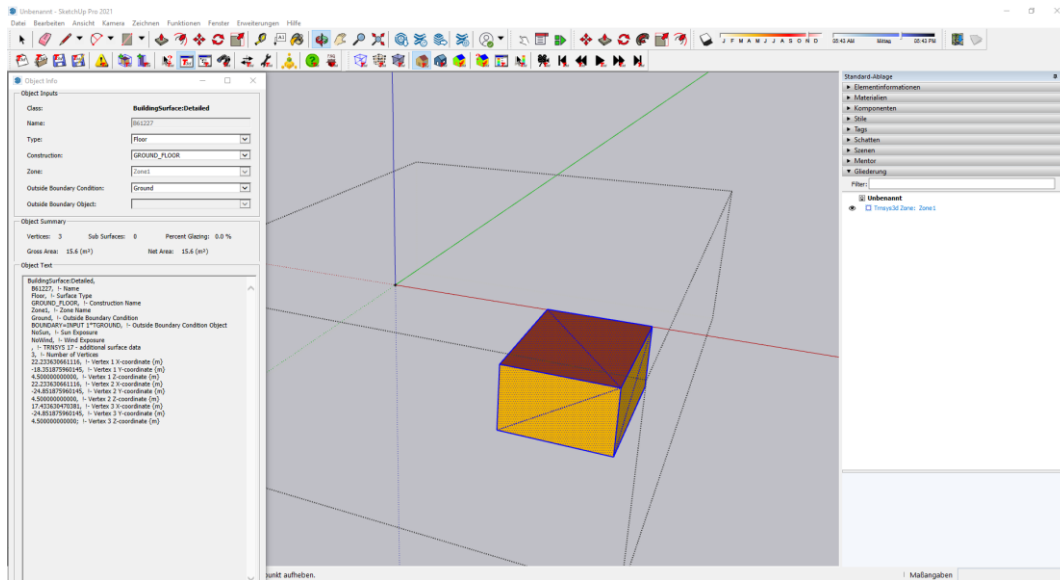

- Activate the zone by double clicking it in the outline (a dotted grey line will outline the zone)

- Select **Edit > Paste in place** and the geometry is now part of the zone.

Explode the copied zone by pressing right mouse button on the group and selecting “explode”. The color of surfaces will now change (grey: floor, beige: wall, dark red: ceiling).

- If the surfaces in the ifc file are triangulated like in the example above, they can simply be merged by deleting the edge that is dividing them. (Caution: this is possible for planar surfaces only)

- If you have an ifc Model, where the Windows are just simple surfaces which lie in the same plane as the wall, you can use the ifcWindow Groups as they are to continue with the following steps. Switch to the other Sketchup with your imported model and "Copy" the window surfaces of the zone you just copied.
- Switch to the Trnsys3d Sketchup window and check that the zone is still active (grey dotted outline). Then, select *Edit > Paste in place*, and the window elements are now windows related to the base surface of the zone. The windows should now be "visually cut out" of the wall.
- Save in Trnsys3d by choosing *Plugins > Trnsys3d > Save* from the main menu.
- Repeat this procedure for relevant zones.
If many zones are going to be copied it is recommended to use the "save as" option for saving intermediate versions of the Trnsys3d files. For checking the *.idf file it might be useful to open it into a new SketchUp file instance with Trnsys3d and make sure that all elements appear correctly.
In addition, it is recommended to split very large projects into pieces for reducing complexity and therewith susceptibility to errors.
- For considering thermal conditions of adjacent spaces automatically the boundary surface of both volumes must lie exactly on top of each but with reversed normal vectors (no distance). (see section matching surfaces). Depending on your original geometry data there might be a distance or difference in size due to construction thickness. Currently, this needs to be adapted manually.

- When all zones are finished, adjust the boundaries and the adjacencies in each Trnsys3d zone, use “Object Info” to assign the Construction, Zone, Outside Boundary Condition and Outside Boundary object. Adjust only the walls, ceilings, roofs, and floors. The integrated windows will adjust themselves.

- Save the Trnsys3d file one final time and *.idf file is now readable for TRNSYS 18
- Import the *.idf file into TRNbuild and use the geometry viewer to visually check the created model.

5.7 Further Information

Trnsys3d is based on the open-source legacy version of the OpenStudio plugin developed by the National Renewable Energy Laboratory for the United States Department of Energy.

Therefore, the documentation of legacy version of the Open Studio plugin is included in the installation for further information. You can access it via *Plugins > Trnsys3d > Further Information* or you can find it in your SketchUp installation directory at `.\Plugins\Trnsys3d\doc\help\index.html`. The documentation includes an extensive reference guide as well as a large collection of tutorials.

Be aware that not all features presented in the documentation are available in Trnsys3d. Features of OpenStudio which can't be used in TRNSYS 18 are disabled or commented out. In addition, some features are modified in order to fit the needs of TRNSYS. OpenStudio itself can't be used for TRNSYS 18

Despite these differences the documentation is very helpful for working with Trnsys3d.
